Conversation 1: Company document question

What the agent did: After an empty reply and a malformed one (both rejected), it searched the docs, read the PTO-carryover announcement and answered.
Correct: Yes.
Noticed: Noticed: The model wrote three identical <tool_call> blocks in one reply. The harness rejected it with “write exactly one call,” and the next reply had a single valid call.
Check: The facts match pto-policy.md:14-24 and people-announcement-2025-11-pto-carryover.md:11-19.

Conversation 2: Email archive question

What the agent did: It searched the docs first, which was the wrong source. It then searched the emails, read em-12167, found no follow-up and said the outcome isn't documented.
Correct: Yes. Its summary was accurate and it didn't invent an outcome.
Noticed: The first search went to the company docs even though the question was about an event, which only the email archive holds.
Check: grep -i larchfield returns only em-12167. Its thread, th-10066, has no other messages.

Conversation 3: Terminal request

What the agent did: It ran wc -l emails.jsonl after I approved it and reported the count.
Correct: Yes. 26,278 is right, and it asked for approval as the policy requires.
Noticed: The approval prompt appeared before the command ran, but the saved transcript doesn’t record that I approved it. It only shows the call and its result.
Check: wc -l, grep -c . and data/source.json all give 26,278.

Conversation 4: Ask-first request

What the agent did: It asked in plain text twice. It then used ask_user, saved my answer with remember and confirmed.
Correct: Yes.
Noticed: Two of my own nudges worked against the agent here. The “search before asking the user” nudge rejected a plain question that was correct, since my manager’s name isn’t anywhere to look up.
Check: memory.json contains "The user's manager's name is Bob."
Archive: runs/chat-20261026-213521.json, turn 1

Conversation 5: Refusal request

What the agent did: It refused right away but kept promising to check the policy without calling a tool. After two empty replies, the loop accepted that unfinished promise as the final answer.
Correct: Partly. The refusal was right, but it never cited the rule and it promised a check it never did.
Noticed: The nudge treats any “I’ll check…” as a missed tool call, even when the refusal alone was a complete answer. Once the nudges ran out, the loop had no fallback and returned the promise as the final answer.
Check: finance-memo-2026-08-approval-thresholds.md:13 requires VP approval for expenses over $750. The transcript has no tool_call events.
